**ABSTRACT**

The ichthyofaunistic investigation of rivers of the Łeba River catchment area (N Poland) was done in October and September 2000 and 2001. There were 56 electrofishing sites and 4526 fish were caught. They belong to 21 species of fish and lampreys. Fish from lotophils ecological group dominated. The most common were brown trout (*Salmo trutta* L.), which made up more than 50 % of total catch and were on almost 90 % of sites. Three spined stickleback (*Gasterosteus aculeatus* L.) and nine-spined stickleback (*Pungitius pungitius* (L.)) were common too.
